**Abstract:** Global continuous control for the finite-time or (local) exponential stabilization of mechanical systems with bounded inputs is achieved involving *desired* conservative-force compensation. With respect to the *on-line* compensation case, the proposed controller entails a closed-loop analysis with considerably higher degree of complexity, whence more involved requirements prove to arise. Other important analytical limitations are further overcome through the developed algorithm. Numerical simulations considering a robotic arm model corroborate the efficiency of the proposed scheme.

Keywords: Finite-time stabilization; mechanical systems; desired conservative-force compensation; bounded inputs.

# **1. INTRODUCTION**

A global continuous state-feedback scheme for the finite-time and exponential stabilization of mechanical systems with bounded inputs was developed and thoroughly motivated in [1]. The explicit consideration of input constraints and the explicit choice on the system trajectory convergence are among the main characteristics that distinguish such an approach from continuous finite-time controllers developed for mechanical systems before its appearance: [2], [3], [4] (see for instance [1,  $[\S1]$  for a brief description of such works). Moreover, while the cited previous approaches mainly rely on the dynamic inversion technique (except for one of the two controllers presented in [2]), the scheme in [1] benefits from the inherent passive nature of mechanical systems. This is so in view of its (saturating) Proportional-Derivative type structure with exclusive compensation of the conservative-force (vector) term, which permits to reshape the closed-loop potential energy so as to set the desired posture as the only equilibrium position on the whole configuration space. The exclusive compensation of the conservative-force term allows to reduce the system model dependence of the designed scheme, consequently simplifying the control structure and decreasing the implied computation burden. However, such advantages could still be improved if the on-line compensation term could be replaced by the conservative-force term evaluated at the desired position. This idea was first introduced in [5] in an unconstrained-input conventional (infinite-time) stabilization framework and, since

then, it has been well appreciated due to its simplicity and simplification improvements. This is the main motivation of this work, where a desired-conservative-forcecompensation extension of the finite-time/exponential stabilization scheme from [1] is developed. Such a design task is not as simple or direct as a simple replacement of the *on-line* compensation term by the *desired* one, since the required (desired) closed-loop equilibrium position is kept, but not its uniqueness. Consequently, further design requirements prove to be needed to ensure that the control-induced potential energy component dominates the open-loop one (in order to solve the uniqueness issue). This was already pointed out in [5], where such a domination goal was shown to be achieved through a P control (vector) term with a stronger growing rate than that of the open-loop conservative force term in any direction (at every point) on the configuration space; in particular, under the simple consideration of uncoupled linear P and D control actions, this was shown to be achieved by simply fixing P gains higher than the highest (induced) norm value of the Jacobian matrix of the conservative force term (assuming that such a Jacobian matrix is bounded) [6]. But the solution of the referred uniqueness issue cannot be that simple in the analytical context considered here in view of the special functions involved to guarantee the achievement of the formulated stabilization goal. This represents an important analytical challenge to which this work succeeds to give a solution with the technical benefits from desired conservativeforce compensation.

We thus propose a global continuous state-feedback scheme with desired conservative-force compensation for the finite-time and exponential stabilization of mechan-

ical systems with bounded inputs. The developed approach implies an important simplification on the control implementation with respect to the on-line compensation version. Its efficiency is further corroborated through simulation results.

## **2. PRELIMINARIES**

Let  $X \in \mathbb{R}^{m \times n}$  and  $y \in \mathbb{R}^n$ .  $X_{ij}$  stands for the element of X at its  $i^{th}$  row and  $j^{th}$  column,  $X_i$  for the  $i^{th}$ row of X and  $y_i$  for the *i*<sup>th</sup> element of y. With m = n, X > 0 denotes that X is positive definite; for a symmetric matrix X,  $\lambda_m(X)$  and  $\lambda_M(X)$  respectively stand for its minimum and maximum eigenvalues.  $0_n$  represents the origin of  $\mathbb{R}^n$  and  $I_n$  the  $n \times n$  identity matrix.  $\mathbb{R}^n_{>0}$  and  $\mathbb{R}^n_{>0}$  denote the set of *n*-tuples with positive and non-negative entries, respectively.  $\|\cdot\|$  stands for the standard Euclidean norm for vectors and induced norm for matrices. Let  $S_c^{n-1} = \{x \in \mathbb{R}^n : ||x|| = c\}$ : an (n-1)-dimensional sphere of radius c > 0 on  $\mathbb{R}^n$ . We denote  $D_g f$  the directional derivative of  $f : \mathbb{R}^n \to \mathbb{R}$ along  $g : \mathbb{R}^n \to \mathbb{R}^n$ , *i.e.*,  $D_g f(x) = \frac{\partial f}{\partial x} g(x)$ . We consider the sign function  $sign(\cdot)$  to be zero at zero, and  $\operatorname{sat}(\varsigma) = \operatorname{sign}(\varsigma) \min\{|\varsigma|, 1\}$  The contents of the next subsections were mostly included in  $[1, \S 2]$ ; for the sake of completeness, they are reproduced here.

#### 2.1 Mechanical systems

Consider the *n*-degree-of-freedom (DOF) fullyactuated mechanical system dynamics

$$H(q)\ddot{q} + C(q,\dot{q})\dot{q} + g(q) = \tau \tag{1}$$

where  $q, \dot{q}, \ddot{q} \in \mathbb{R}^n$  are the position (generalized coordinates), velocity, and acceleration vectors; the inertial matrix  $H(q) \in \mathbb{R}^{n \times n}$  is a continuously differentiable positive definite symmetric matrix function, such that  $H(q) \ge \mu_m I_n, \forall q \in \mathbb{R}^n$ , for some  $\mu_m > 0$ ; the Coriolis and centrifugal effect matrix  $C(q, \dot{q}) \in \mathbb{R}^{n \times n}$ , defined through the Christoffel symbols of the first kind, satisfies  $\dot{H}(q, \dot{q}) = C(q, \dot{q}) + C^T(q, \dot{q}), \forall q, \dot{q} \in \mathbb{R}^n$ , and consequently

$$z^{T}\left[\frac{1}{2}\dot{H}(x,y) - C(x,y)\right]z = 0$$
(2a)

 $\forall x, y, z \in \mathbb{R}^n$ , where  $\dot{H} : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^{n \times n}$ , with  $\dot{H}_{ij}(q,\dot{q}) = \frac{\partial \dot{H}_{ij}}{\partial q}(q)\dot{q}, i, j = 1, \dots, n$ ,

$$\|C(x,y)\| \le \psi(x)\|y\| \tag{2b}$$

for some  $\psi : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ , and C(x, y)z = C(x, z)y,  $\forall x, y, z \in \mathbb{R}^n$ , whence we have that

$$C(q, a\dot{q})b\dot{q} = C(q, b\dot{q})a\dot{q} = C(q, ab\dot{q})\dot{q} = C(q, \dot{q})ab\dot{q}$$
(3)

 $\forall q, \dot{q} \in \mathbb{R}^n, \forall a, b \in \mathbb{R}; g(q) = \nabla \mathcal{U}_{ol}(q)$ , with  $\mathcal{U}_{ol} : \mathbb{R}^n \to \mathbb{R}$  being the potential energy function of the

open-loop system, or equivalently  $\mathcal{U}_{ol}(q) = \mathcal{U}_{ol}(q_0) + \int_{q_0}^q g^T(z) dz$ , for any  $q, q_0 \in \mathbb{R}^n$ ; and  $\tau \in \mathbb{R}^n$  is the external input (generalized) force vector.

We consider the (realistic) bounded input case, where each input  $\tau_i$  is constrained by a saturation bound  $T_i > 0$ . More precisely, letting  $u_i$  represent the control variable (controller output) relative to the  $i^{\text{th}}$  degree of freedom, we have that

$$\tau_i = T_i \operatorname{sat}(u_i/T_i) \tag{4}$$

Assumption 2.1. H(q) is bounded, i.e.  $||H(q)|| \le \mu_M$ ,  $\forall q \in \mathbb{R}^n$ , for some  $\mu_M \ge \mu_m > 0$ .

Assumption 2.2.  $\psi(\cdot)$  in (2b) is bounded and consequently  $||C(x,y)|| \leq k_C ||y||, \forall x, y \in \mathbb{R}^n$ , for some  $k_C \geq 0$ .

**Assumption 2.3.** The gravity force vector is a continuously differentiable bounded vector function with bounded Jacobian matrix  $\frac{\partial g}{\partial q}$ , or equivalently:  $|g_i(q)| \leq B_{gi}, \forall q \in \mathbb{R}^n$ , for some non-negative constant  $B_{gi}$ ;  $\left\|\frac{\partial g}{\partial q}(q)\right\| \leq k_g, \forall q \in \mathbb{R}^n$ , for some non-negative constant  $k_g$ , and consequently  $\|g(x) - g(y)\| \leq k_g \|x - y\|$ ,  $\forall x, y \in \mathbb{R}^n$ .

Assumption 2.4.  $T_i > \eta B_{gi}$ ,  $i = 1, \ldots, n$ , with  $\eta \ge 1$ .

Assumptions 2.1–2.3 apply *e.g.* for robot manipulators having only revolute joints.

### 2.2 Local homogeneity, finite-time/δ-exponential stability

This work is developed within the analytical framework of *local homogeneity*, which states a formal analytical platform permitting to handle vector fields with bounded components [7]. Definitions and results in such an analytical context are strongly related to *family of dilations*  $\delta_{\varepsilon}^{r}$ , defined as  $\delta_{\varepsilon}^{r}(x) = (\varepsilon^{r_1}x_1, \ldots, \varepsilon^{r_n}x_n)^T$ ,  $\forall x \in \mathbb{R}^n, \forall \varepsilon > 0$ , with  $r = (r_1, \ldots, r_n)^T$ , where the *dilation coefficients*  $r_1, \ldots, r_n$  are positive scalars.

**Definition 2.1.** [7] A function  $V : \mathbb{R}^n \to \mathbb{R}$ , resp. vector field  $f = \sum_{i=1}^n f_i \frac{\partial}{\partial x_i}$  (with  $f_i : \mathbb{R}^n \to \mathbb{R}$ ), is locally homogeneous of degree  $\alpha$  with respect to  $\delta_{\varepsilon}^r$  (locally *r*-homogeneous of degree  $\alpha$ ), if there exists an open neighborhood of the origin  $D \subset \mathbb{R}^n$  (domain of homogeneity), such that, for every  $x \in D$  and all  $\varepsilon \in (0, 1]$ :  $\delta_{\varepsilon}^r(x) \in D$ , and  $V(\delta_{\varepsilon}^r(x)) = \varepsilon^{\alpha}V(x)$ , resp.,  $f_i(\delta_{\varepsilon}^r(x)) = \varepsilon^{\alpha+r_i}f_i(x)$ , i = 1, ..., n.

Fundamental concepts involved in the analytical context underlying this work are those of *homogeneous* norm (a positive definite continuous function being r-homogeneous of degree 1) [8], [9], denoted  $\|\cdot\|_r$ , and r-homogeneous (n-1)-sphere of radius c > 0:  $S_{r,c}^{n-1} = \{x \in \mathbb{R}^n : \|x\|_r = c\}$ .

Consider an *n*-th order autonomous system

$$\dot{x} = f(x) \tag{5}$$

where f is a vector field being continuous on an open neighborhood of the origin  $\mathcal{D} \subset \mathbb{R}^n$  and such that  $f(0_n) = 0_n$ , and let  $x(t; x_0)$  represent the system solution with initial condition  $x(0; x_0) = x_0$ . An important definition for this work is that of a (globally) *finite-time* equilibrium as stated in [10].

**Remark 2.1.** The origin is a globally finite-time stable equilibrium of system (5) if and only if it is globally asymptotically stable and finite-time stable.  $\triangle$ 

**Theorem 2.1.** [7] Consider system (5) with  $\mathcal{D} = \mathbb{R}^n$ . Suppose that f is a locally r-homogeneous vector field of degree  $\alpha$  with domain of homogeneity  $D \subset \mathbb{R}^n$ . Then, the origin is a globally finite-time stable equilibrium of system (5) if and only if it is globally asymptotically stable and  $\alpha < 0$ .

The next definition is stated under the additional consideration that, for some  $r \in \mathbb{R}^n_{>0}$ , f in (5) is locally r-homogeneous with domain of homogeneity  $D \subset \mathcal{D}$ .

**Definition 2.2.** [9], [8] The equilibrium point  $x = 0_n$ of (5) is  $\delta$ -exponentially stable with respect to the homogeneous norm  $\|\cdot\|_r$  if there exist a neighborhood of the origin,  $\mathcal{V} \subset \mathcal{D}$ , and constants  $a \ge 1$  and b > 0 such that  $\|x(t; x_0)\|_r \le a \|x_0\|_r e^{-bt}, \forall t \ge 0, \forall x_0 \in \mathcal{V}.$ 

**Remark 2.2.** If f in (5) is locally r-homogeneous of degree  $\alpha = 0$  with dilation coefficients  $r_i = r_0, \forall i \in \{1, \ldots, n\}$ , for some  $r_0 > 0$ , then the origin turns out to be exponentially stable (in the standard sense [11, Definition 4.5]) if and only if it is  $\delta$ -exponentially stable [1, Remark 2.5].

Consider an *n*-th order autonomous system of the form

$$\dot{x} = f(x) + \hat{f}(x) \tag{6}$$

where f and  $\hat{f}$  are continuous vector fields on  $\mathbb{R}^n$  such that  $f(0_n) = \hat{f}(0_n) = 0_n$ .

**Lemma 2.1.** [1, Lemma 2.2] Suppose that, for some  $r \in \mathbb{R}^n_{>0}$ , f in (6) is a locally r-homogeneous vector field of degree  $\alpha < 0$ , resp.  $\alpha = 0$ , with domain of homogeneity  $D \subset \mathbb{R}^n$ , and that  $0_n$  is a globally asymptotically, resp.  $\delta$ -exponentially, stable equilibrium of  $\dot{x} = f(x)$ . Then, the origin is a finite-time, resp.  $\delta$ -exponentially, stable equilibrium of system (6) if

$$\lim_{\varepsilon \to 0^+} \frac{\hat{f}_i(\delta^r_\varepsilon(x))}{\varepsilon^{\alpha + r_i}} = 0$$

 $i = 1, \ldots, n$ ,  $\forall x \in S_c^{n-1}$ , resp.  $\forall x \in S_{r,c}^{n-1}$ , for some c > 0 such that  $S_c^{n-1} \subset D$ , resp.  $S_{r,c}^{n-1} \subset D$ .

**Remark 2.3.** Notice that the condition required by Lemma 2.1 may be equivalently verified through the satisfaction of

$$\lim_{\varepsilon \to 0^+} \left\| \varepsilon^{-\alpha} \operatorname{diag} \left[ \varepsilon^{-r_1}, \dots, \varepsilon^{-r_n} \right] \widehat{f}(\delta^r_{\varepsilon}(x)) \right\| = 0$$
  
$$\forall x \in S^{n-1}_c \text{ (resp. } S^{n-1}_{r,c} \text{).} \qquad \bigtriangleup$$

#### 2.3 Scalar functions with particular properties

**Definition 2.3.** A continuous scalar function  $\sigma : \mathbb{R} \to \mathbb{R}$ will be said to be:

1. bounded —by M— if  $|\sigma(\varsigma)| \leq M$ ,  $\forall \varsigma \in \mathbb{R}$ , for some positive constant M;

2. strictly passive if  $\varsigma \sigma(\varsigma) > 0$ ,  $\forall \varsigma \neq 0$ ;

3. strongly passive if it is a strictly passive function satisfying  $|\sigma(\varsigma)| \geq \kappa |a \operatorname{sat}(\varsigma/a)|^b = \kappa (\min\{|\varsigma|, a\})^b$ ,  $\forall \varsigma \in \mathbb{R}$ , for some positive constants  $\kappa$ , a and b.

**Remark 2.4.** Equivalent characterizations of strictly passive functions are:  $\varsigma \sigma(\varsigma) > 0 \iff \operatorname{sign}(\varsigma) \sigma(\varsigma) > 0 \iff \operatorname{sign}(\sigma(\varsigma)) = \operatorname{sign}(\varsigma), \forall \varsigma.$ 

**Lemma 2.2.** [1, Lemma 2.3] Let  $\sigma : \mathbb{R} \to \mathbb{R}$ ,  $\sigma_0 : \mathbb{R} \to \mathbb{R}$  and  $\sigma_1 : \mathbb{R} \to \mathbb{R}$  be strongly passive functions and k be a positive constant. Then:

- 1.  $\int_0^{\varsigma} \sigma(k\nu) d\nu > 0, \, \forall \varsigma \neq 0;$
- 2.  $\int_{0}^{\varsigma} \sigma(k\nu) d\nu \to \infty \text{ as } |\varsigma| \to \infty;$
- *3.*  $\sigma_0 \circ \sigma_1$  *is strongly passive.*

#### **3. THE PROPOSED CONTROL SCHEME**

Consider the following SP-SD type controller with *desired* conservative-force compensation

$$u(q, \dot{q}) = -s_1(K_1 \bar{q}) - s_2(K_2 \dot{q}) + g(q_d)$$
(7)

where  $\bar{q} = q - q_d$ , for any constant (desired equilibrium position)  $q_d \in \mathbb{R}^n$ ;  $K_i = \text{diag}[k_{i1}, \ldots, k_{in}]$ , i = 1, 2, are positive definite diagonal matrices *i.e.*  $K_i = \text{diag}[k_{i1}, \ldots, k_{in}], k_{ij} > 0, i = 1, 2,$  $j = 1, \ldots, n$ — with  $K_1$  involved in an additional requirement stated below (through (9)); for any  $x \in \mathbb{R}^n$ ,  $s_i(x) = (\sigma_{i1}(x_1), \ldots, \sigma_{in}(x_n))^T$ , i = 1, 2, with, for each  $j = 1, \ldots, n, \sigma_{1j}$  being strongly passive and  $\sigma_{2j}$ being strictly passive functions such that

$$B_j \triangleq \sup_{(\varsigma_1, \varsigma_2) \in \mathbb{R}^2} \left| \sigma_{1j}(\varsigma_1) + \sigma_{2j}(\varsigma_2) \right| < T_j - B_{gj} \tag{8}$$

both being locally Lipschitz-continuous on  $\mathbb{R} \setminus \{0\}$ ; and with, for each j = 1, ..., n,  $k_{1j}$  and  $\sigma_{1j}$  additionally required to be such that, for all  $\varsigma \in \mathbb{R}$ ,

$$\left|\sigma_{1j}(k_{1j}\varsigma)\right| > \min\left\{k_g|\varsigma|, 2B_{gj}\right\}$$
(9)

Remark 3.1. From the above formulation, we have that

$$2B_{gj} < |\sigma_{1j}(k_{1j}\varsigma)| \le B_j < T_j - B_{gj}$$

 $\forall |\varsigma| \geq 2B_{gj}/k_g$ , whence one sees that Assumption 2.4 with  $\eta = 3$  is a necessary condition for the feasibility of the simultaneous fulfilment of (8) and (9).  $\triangle$ 

**Remark 3.2.** Inequality (9) implies the existence of constants  $\hat{k}_{1j} > k_g$  and  $b_j > 2B_{gj}$  such that  $|\sigma_{1j}(k_{1j}\varsigma)| \ge \min\{\hat{k}_{1j}|\varsigma|, b_j\} > \min\{k_g|\varsigma|, 2B_{gj}\}, \forall \varsigma \neq 0.$ 

**Proposition 3.1.** Consider system (1),(4) in closed loop with the proposed control law (7), under Assumptions 2.1–2.3 and 2.4 with  $\eta = 3$ , and the above stated design specifications. Thus, global asymptotic stability of the closed-loop trivial solution  $\bar{q}(t) \equiv 0_n$  is guaranteed with  $|\tau_j(t)| = |u_j(t)| < T_j, j = 1, ..., n, \forall t \ge 0$ .

*Proof.* Observe that —for every j = 1, ..., n— by (8), we have that, for any  $(q, \dot{q}) \in \mathbb{R}^n \times \mathbb{R}^n$  and any  $q_d \in \mathbb{R}^n$ :  $|u_j(q, \dot{q})| \leq |\sigma_{1j}(k_{1j}\bar{q}_j) + \sigma_{2j}(k_{2j}\dot{q}_j)| + |g_j(q_d)| \leq B_j + B_{gj} < T_j$ . From this and (4), one sees that  $T_j > |u_j(q, \dot{q})| = |u_j| = |\tau_j|, \forall (q, \dot{q}) \in \mathbb{R}^n \times \mathbb{R}^n$ , which shows that, along the system trajectories,  $|\tau_j(t)| = |u_j(t)| < T_j, j = 1, ..., n, \forall t \geq 0$ . Hence, the closed-loop dynamics takes the form

$$H(q)\ddot{q} + C(q,\dot{q})\dot{q} + g(q) = -s_1(K_1\bar{q}) - s_2(K_2\dot{q}) + g(q_d)$$

By defining  $x_1 = \bar{q}$ ,  $x_2 = \dot{q}$ , and  $x = (x_1^T, x_2^T)^T$  the closed-loop dynamics adopts the form of (6) with

$$f(x) = \begin{pmatrix} f_{(1)}(x) \\ f_{(2)}(x) \end{pmatrix} , \quad \hat{f}(x) = \begin{pmatrix} \hat{f}_{(1)}(x) \\ \hat{f}_{(2)}(x) \end{pmatrix}$$
(10)

where  $f_{(1)}(x) = x_2$ ,  $f_{(2)}(x) = -H^{-1}(q_d) [s_1(K_1x_1) + s_2(K_2x_2)]$ ,  $\hat{f}_{(1)}(x) = 0_n$ , and

$$\hat{f}_{(2)}(x) = -H(x_1 + q_d)[C(x_1 + q_d, x_2)x_2 + g(x_1 + q_d) - g(q_d)] - \mathcal{H}(x_1)[s_1(K_1x_1) + s_2(K_2x_2)]$$
(11)

with

$$\mathcal{H}(x_1) = H^{-1}(x_1 + q_d) - H^{-1}(q_d)$$
(12)

Thus, the closed-loop stability property stated through Proposition 3.1 is corroborated by showing that  $x = 0_{2n}$  is a globally asymptotically stable equilibrium of the state equation  $\dot{x} = f(x) + \hat{f}(x)$ , which is proven through the following theorem.

**Theorem 3.1.** Under the stated specifications, the origin is a globally asymptotically stable equilibrium of  $\dot{x} = f(x) + \ell \hat{f}(x), \forall \ell \in \{0, 1\}$ , with f(x) and  $\hat{f}(x)$  defined through Eqs. (10).

*Proof.* For every  $\ell \in \{0, 1\}$ , let us define the continuously differentiable scalar function

$$V_{\ell}(x_1, x_2) = \frac{1}{2} x_2^T H(\ell x_1 + q_d) x_2 + \mathcal{U}_{\ell}(x_1)$$
(13)

where

$$\mathcal{U}_{\ell}(x_1) \triangleq \int_{0_n}^{x_1} s_1^T(K_1 z) dz + \ell \,\mathcal{U}(x_1) \tag{14}$$

$$\int_{0_n}^{x_1} s_1^T(K_1 z) dz = \sum_{j=1}^n \int_0^{x_{1j}} \sigma_{1j}(k_{1j} z_j) dz_j,$$
  
$$\mathcal{U}(x_1) \triangleq \mathcal{U}_{\rm ol}(x_1 + q_d) - \mathcal{U}_{\rm ol}(q_d) - g^T(q_d) x_1 \qquad (15a)$$

$$= \int_{0_n}^{x_1} \left[ g(z+q_d) - g(q_d) \right]^T dz$$
 (15b)

$$= \int_{0_n}^{x_1} \left[ \int_{0_n}^z \frac{\partial g}{\partial q} (\bar{z} + q_d) d\bar{z} \right]^T dz$$
(15c)

Observe from Eqs. (15) and Assumption 2.3 that

$$\mathcal{U}(x_1) \leq \int_{0_n}^{x_1} \left[ \int_{0_n}^z \left\| \frac{\partial g}{\partial q} (\bar{z} + q_d) \right\| d\bar{z} \right]^T dz$$
$$\leq \int_{0_n}^{x_1} k_g z^T dz = \sum_{j=1}^n \int_0^{x_{1j}} k_g z_j dz_j \tag{16}$$

 $\forall x_1 \in \mathbb{R}^n$  (from (15c)), and simultaneously that

$$\begin{aligned} \mathcal{U}(x_1) &\leq \sum_{j=1}^n \int_0^{x_{1j}} \operatorname{sign}(z_j) \big| g_j(z+q_d) - g_j(q_d) \big| dz_j \\ &\leq \sum_{j=1}^n \int_0^{x_{1j}} \operatorname{sign}(z_j) 2B_{gj} dz_j \end{aligned}$$

 $\forall x_1 \in \mathbb{R}^n$  (from (15b)). From these inequalities, the satisfaction of (9), and Remark 3.2, we have that

$$\mathcal{U}_{\ell}(x_{1}) \geq \sum_{j=1}^{n} \int_{0}^{x_{1j}} \operatorname{sign}(z_{j}) \min \left\{ (\hat{k}_{1j} - \ell k_{g}) |z_{j}|, \\ (b_{j} - 2\ell B_{gj}) \right\} dz_{j}$$
$$= \sum_{j=1}^{n} w_{\ell j}(x_{1j}) \triangleq S_{\ell}(x_{1})$$
(17a)

with

$$w_{\ell j}(x_{1j}) = \begin{cases} \frac{\bar{k}_{\ell j}}{2} x_{1j}^2 & \text{if } |x_{1j}| \le \bar{b}_{\ell j}/\bar{k}_{\ell j} \\ \bar{b}_{\ell j} \left[ |x_{1j}| - \bar{b}_{\ell j}/(2\bar{k}_{\ell j}) \right] & \text{if } |x_{1j}| > \bar{b}_{\ell j}/\bar{k}_{\ell j} \end{cases}$$
(17b)

for some  $\hat{k}_{1j} > k_g$  and  $b_j > 2B_{gj}$ , and any positive constants  $\bar{k}_{\ell j} \leq \hat{k}_{1j} - \ell k_g$  and  $\bar{b}_{\ell j} \leq b_j - 2\ell B_{gj}$ .

**Remark 3.3.** Note from expressions (17) that  $S_{\ell}(x_1)$ ,  $\ell = 0, 1$ , are positive definite radially unbounded functions. Observe further that (involving previous arguments and Remark 2.4)

$$D_{x_1} \mathcal{U}_{\ell}(x_1) = x_1^T \left[ s_1(K_1 x_1) + \ell \left( g(x_1 + q_d) - g(q_d) \right) \right]$$
  

$$\geq \sum_{j=1}^n |x_{1j}| \left[ \left| \sigma_{1j}(k_{1j} x_{1j}) \right| - \ell |g_j(x_1 + q_d) - g_j(q_d) \right| \right]$$
  

$$\geq \sum_{j=1}^n |x_{1j}| \min \left\{ \bar{k}_{\ell j} |x_{1j}|, \bar{b}_{\ell j} \right\} > 0$$
(18)

 $\begin{array}{l} \forall x_1 \neq 0_n, \text{ whence one sees that, for every } \ell = 0, 1, \\ \nabla_{x_1} \mathcal{U}_\ell(x_1) = s_1(K_1 x_1) + \ell \big[ g(x_1 + q_d) - g(q_d) \big] = \\ 0_n \iff x_1 = 0_n \qquad \qquad \bigtriangleup$ 

Thus, from Eqs. (13) and (17) and the properties of H(q) we get that

$$V_{\ell}(x_1, x_2) \ge \frac{\mu_m}{2} \|x_2\|^2 + S_{\ell}(x_1)$$
(19)

whence positive definiteness and radial unboundedness of  $V_{\ell}$ ,  $\ell = 0, 1$ , is concluded. Further, for every  $\ell \in \{0, 1\}$ , the derivative of  $V_{\ell}$  along the trajectories of  $\dot{x} = f(x) + \ell \hat{f}(x)$ , is obtained, after basic developments, as

$$\dot{V}_{\ell}(x_1, x_2) = -x_2^T s_2(K_2 x_2) = -\sum_{j=1}^n x_{2j} \sigma_{2j}(k_{2j} x_{2j})$$

where, in the case of  $\ell = 1$ , (2a) has been ap-Notice, from the strictly passive characplied. ter of  $\sigma_{2j}$ , that  $V_{\ell}(x_1, x_2) \leq 0$ ,  $\forall (x_1, x_2)$  $\in$  $\times \mathbb{R}^n$ , with  $Z_\ell \triangleq \{(x_1, x_2) \in \mathbb{R}^n \times$  $\mathbb{R}^{n}$  $\mathbb{R}^n$  :  $\dot{V}_{\ell}(x_1, x_2) = 0$  = { $(x_1, x_2) \in \mathbb{R}^n$  $\times \mathbb{R}^n$  :  $x_2 = 0_n$ . Further, from the system dynamics  $\dot{x} = f(x) + \ell \hat{f}(x)$  —due to the positive definiteness of H and Remark 3.3— one sees that  $x_2(t) \equiv 0_n$  $\implies$  $\dot{x}_2(t) \equiv 0_n$  $\implies$  $s_1(K_1x_1(t)) + \ell[g(x_1(t) + q_d) - g(q_d)] \equiv$  $0_n$  $\iff x_1(t) \equiv \overline{0}_n$  (which shows that  $(x_1, x_2)(t) \equiv$  $(0_n, 0_n)$  is the only system solution completely remaining in  $Z_{\ell}$ ), and corroborates that at any  $(x_1, x_2) \in$  $\{(\bar{q}, \dot{q}) \in Z_{\ell} : \bar{q} \neq 0_n\}$ , the resulting unbalanced force terms act on the closed-loop dynamics  $|\dot{x} = f(x_1, 0_n) +$  $\ell f(x_1, 0_n)$  with  $(x_1, x_2) \neq (0_n, 0_n)$ , forcing the system trajectories to leave  $Z_{\ell}$ , whence  $\{(0_n, 0_n)\}$  is concluded to be the only invariant set in  $Z_{\ell}$ ,  $\ell = 0, 1$ . Therefore, by the invariance theory [12, §7.2],  $x = 0_{2n}$  is concluded to be a globally asymptotically stable equilibrium of both the state equation  $\dot{x} = f(x)$  and the (closed-loop) system  $\dot{x} = f(x) + \hat{f}(x).$ 

#### 3.1 Finite-time/exponential stabilization

**Proposition 3.2.** Consider the proposed control scheme under the additional consideration that, for every  $j = 1, \ldots, n$ ,  $\sigma_{ij}$ , i = 1, 2, are locally  $r_i$ -homogeneous of degree  $\alpha_j = 2r_2 - r_1$ —i.e.  $r_{1j} = r_1, r_{2j} = r_2$  and  $\alpha_{1j} = \alpha_{2j} = \alpha_j = 2r_2 - r_1$  for all  $j = 1, \ldots, n$ — with domain of homogeneity  $D_{ij} = \{\varsigma \in \mathbb{R} : |\varsigma| < L_{ij} \in (0, \infty]\}$ , for some dilation coefficients  $r_i > 0$ , i = 1, 2, such that  $\alpha_j = 2r_2 - r_1 > 0 > r_2 - r_1$ . Thus, global finite-time stability of the closed-loop trivial solution  $\bar{q}(t) \equiv 0_n$  is guaranteed with  $|\tau_j(t)| = |u_j(t)| < T_j, j = 1, \ldots, n$ ,  $\forall t \ge 0$ .

*Proof.* Note that Proposition 3.1 holds and consequently  $|\tau_j(t)| = |u_j(t)| < T_j, j = 1, \dots, n, \forall t \ge 0$ . Then, all that remains to be proven is that the additional considerations give rise to finite-time stabilization. In this direction, let  $\hat{r}_i = (r_{i1}, \dots, r_{in})^T$ ,  $i = 1, 2, r = (\hat{r}_1^T, \hat{r}_2^T)^T$ ,  $D \triangleq \{(x_1, x_2) \in \mathbb{R}^n \times \mathbb{R}^n : K_i x_i \in D_{i1} \times \dots \times D_{in}, i = 0\}$  $\{1,2\} = \{(x_1,x_2) \in \mathbb{R}^n \times \mathbb{R}^n : |x_{1j}| < L_{1j}/k_{1j},$  $|x_{2j}| < L_{2j}/k_{2j}, j = 1, ..., n$ , and consider the previously defined state (vector) variables and the consequent closed-loop state-space representation  $\dot{x} = f(x) + f(x)$ , with f and  $\hat{f}$  as defined through Eqs. (10). Since D defines an open neighborhood of the origin, there exists  $\rho > 0$  such that  $B_{\rho} \triangleq \{x \in \mathbb{R}^{2n} : \|x\| < \rho\} \subset D.$ Moreover, for every  $x \in B_{\rho}$  and all  $\varepsilon \in (0, 1]$ , we have that  $\delta_{\varepsilon}^{r}(x) \in B_{\rho}$  (since  $\|\delta_{\varepsilon}^{r}(x)\| < \|x\|, \forall \varepsilon \in (0,1)$ ), and, for every  $j \in \{1, \ldots, n\}$ ,

$$f_j(\delta_{\varepsilon}^r(x)) = \varepsilon^{r_{2j}} x_{2j} = \varepsilon^{(r_2 - r_1) + r_{1j}} f_j(x)$$

$$f_{n+j}(\delta_{\varepsilon}^{r}(x)) = -H_{j}^{-1}(q_{d}) \left( s_{1}(\varepsilon^{r_{1}}K_{1}x_{1}) + s_{2}(\varepsilon^{r_{2}}K_{2}x_{2}) \right) \\ = -\varepsilon^{\alpha_{1}}H_{j}^{-1}(q_{d}) \left( s_{1}(K_{1}x_{1}) + s_{2}(K_{2}x_{2}) \right) \\ = \varepsilon^{(r_{2}-r_{1})+r_{2j}} f_{n+j}(x)$$

whence one concludes that f is a locally r-homogeneous vector field of degree  $\alpha = r_2 - r_1$ , with domain of homogeneity  $B_{\rho}$ . Hence, by Theorems 2.1 and 3.1, the origin of system  $\dot{x} = f(x)$  is concluded to be a globally finite-time stable equilibrium since  $r_2 - r_1 < 0$ . Thus, by Theorem 3.1, Lemma 2.1, and Remarks 2.1 and 2.3, we conclude that the origin of the closed-loop system  $\dot{x} = f(x) + \hat{f}(x)$  is a global finite-time stable equilibrium, provided that  $r_2 - r_1 < 0$ , if

$$\mathcal{L}_{0} \triangleq \lim_{\varepsilon \to 0^{+}} \left\| \varepsilon^{-\alpha} \delta_{\varepsilon}^{-\hat{r}_{2}} \left( \hat{f}_{(2)}(\delta_{\varepsilon}^{r}(x)) \right) \right\|$$
$$= \lim_{\varepsilon \to 0^{+}} \left\| \varepsilon^{-\alpha - r_{2}} \hat{f}_{(2)}(\delta_{\varepsilon}^{r}(x)) \right\|$$
$$= \lim_{\varepsilon \to 0^{+}} \varepsilon^{r_{1} - 2r_{2}} \left\| \hat{f}_{(2)}(\delta_{\varepsilon}^{r}(x)) \right\| = 0$$
(20)

for all  $x \in S_c^{2n-1} = \{x \in \mathbb{R}^{2n} : ||x|| = c\}$ , for some c > 0 such that  $S_c^{2n-1} \subset D$ . Hence, under the consideration of (11) and (3), we have for all such  $x \in S_c^{2n-1}$ :

$$\begin{split} \left\| \hat{f}_{(2)}(\delta_{\varepsilon}^{r}(x)) \right\| \\ &\leq \left\| H^{-1}(\varepsilon^{r_{1}}x_{1} + q_{d})C(\varepsilon^{r_{1}}x_{1} + q_{d}, x_{2})\varepsilon^{2r_{2}}x_{2} \right\| \\ &+ \left\| H^{-1}(\varepsilon^{r_{1}}x_{1} + q_{d}) \right\| \left\| g(\varepsilon^{r_{1}}x_{1} + q_{d}) - g(q_{d}) \right\| \\ &+ \left\| \mathcal{H}(\varepsilon^{r_{1}}x_{1}) \left[ \varepsilon^{\alpha_{1}}s_{1}(K_{1}x_{1}) + \varepsilon^{\alpha_{2}}s_{2}(K_{2}x_{2}) \right] \right\| \\ &\leq \varepsilon^{2r_{2}} \left\| H^{-1}(\varepsilon^{r_{1}}x_{1} + q_{d})C(\varepsilon^{r_{1}}x_{1} + q_{d}, x_{2})x_{2} \right\| \\ &+ \left\| H^{-1}(\varepsilon^{r_{1}}x_{1} + q_{d}) \right\| k_{g}\varepsilon^{r_{1}} \|x_{1}\| \\ &+ \varepsilon^{2r_{2}-r_{1}} \left\| \mathcal{H}(\varepsilon^{r_{1}}x_{1}) \left[ s_{1}(K_{1}x_{1}) + s_{2}(K_{2}x_{2}) \right] \right\| \end{split}$$

and consequently, from (20) (recall that  $r_1 > r_2 > 0$ ),

$$\mathcal{L}_{0} \leq \lim_{\varepsilon \to 0^{+}} \varepsilon^{r_{1}} \left\| H^{-1}(\varepsilon^{r_{1}}x_{1} + q_{d})C(\varepsilon^{r_{1}}x_{1} + q_{d}, x_{2})x_{2} \right\| \\
+ k_{g} \|x_{1}\| \lim_{\varepsilon \to 0^{+}} \varepsilon^{2(r_{1} - r_{2})} \left\| H^{-1}(\varepsilon^{r_{1}}x_{1} + q_{d}) \right\| \\
+ \lim_{\varepsilon \to 0^{+}} \left\| \mathcal{H}(\varepsilon^{r_{1}}x_{1}) \left[ s_{1}(K_{1}x_{1}) + s_{2}(K_{2}x_{2}) \right] \right\| \\
\leq \left\| H^{-1}(q_{d})C(q_{d}, x_{2})x_{2} \right\| \lim_{\varepsilon \to 0^{+}} \varepsilon^{r_{1}} \\
+ k_{g} \|x_{1}\| \left\| H^{-1}(q_{d}) \right\| \lim_{\varepsilon \to 0^{+}} \varepsilon^{2(r_{1} - r_{2})} \\
+ \left\| s_{1}(K_{1}x_{1}) + s_{2}(K_{2}x_{2}) \right\| \lim_{\varepsilon \to 0^{+}} \left\| \mathcal{H}(\varepsilon^{r_{1}}x_{1}) \right\| \\
\leq \left\| s_{1}(K_{1}x_{1}) + s_{2}(K_{2}x_{2}) \right\| \cdot \left\| \mathcal{H}(0_{n}) \right\| = 0$$
(21)

(note, from (12), that  $||\mathcal{H}(0_n)|| = ||H^{-1}(q_d) - H^{-1}(q_d)|| = 0$ ), which completes the proof.  $\Box$ 

**Corollary 3.1.** Consider the proposed control scheme taking  $\sigma_{ij}$ ,  $i = 1, 2, j = 1, \ldots, n$ , such that

$$\sigma_{ij}(\varsigma) = sign(\varsigma)|\varsigma|^{\beta_{ij}} \quad \forall |\varsigma| \le L_{ij} \in (0,\infty)$$
(22)

with constants  $\beta_{ij}$  such that

$$0 < \beta_{1j} \le 1$$
 ,  $\beta_{2j} = \frac{2\beta_{1j}}{1 + \beta_{1j}}$  (23)

Thus,  $|\tau_i(t)| = |u_i(t)| < T_i, j = 1, ..., n, \forall t \ge 0$ , and the closed-loop trivial solution  $\bar{q}(t) \equiv 0_n$  is:

1. globally finite-time stable if  $0 < \beta_1 < 1$ ;

2. globally asymptotically stable and (locally) exponen*tially stable if*  $\beta_1 = 1$ .

Item 1 of Corollary 3.1 is proven by corroborating that, under the stated conditions, for every  $j = 1, \ldots, n$ and any  $r_1 > 0$ , by taking  $r_{1i} = r_1$  and  $r_{2i} = r_2 =$  $(1+\beta_1)r_1/2$ , the requirements of Proposition 3.2 are satisfied with  $0 < \beta_1 < 1 \implies r_2 - r_1 < 0 < 2r_2 - r_1$ . On the other hand, note that with  $r_2 = r_1$  —or analogously  $\beta_1 = 1$  in the context of Corollary 3.1— we have that  $\varepsilon^{r_2-r_1} = 1, \forall \varepsilon > 0$ . Hence, in this case, developments analog to those giving rise to inequalities (21) lead to  $\mathcal{L}_0 \leq k_q \|x_1\| \|H^{-1}(q_d)\|$ , and consequently, Lemma 2.1 (under the consideration of Remark 2.2) cannot be applied to conclude (local) exponential stability (contrarily to the on-line conservative-force compensation case of [1]). However, while the global asymptotic stability follows from Proposition 3.1, the (local) exponential stability stated through item 2 of Corollary 3.1 is proven by showing that, for a sufficiently small value of  $\varepsilon$ ,

$$V_2(x_1, x_2) = V_1(x_1, x_2) + \epsilon x_1^T H(x_1 + q_d) x_2$$

—with  $V_1$  as defined through Eq. (13)— is a suitable strict Luapunov function of the closed-loop system, on a neighborhood of the origin  $0_{2n}$ . In particular, with

$$\begin{aligned} \epsilon &< \min\{\epsilon_{1}, \epsilon_{2}\} \\ \epsilon_{1} &= \frac{\left[\bar{k}_{1m}\mu_{m}\right]^{1/2}}{\mu_{M}} \\ \epsilon_{2} &= \frac{\bar{k}_{1m}k_{2m}}{\bar{k}_{1m}k_{C}\varrho + \bar{k}_{1m}\mu_{M} + k_{2M}^{2}/4} \\ \bar{k}_{1m} &= \min_{j}\{\bar{k}_{1j}\}, \ k_{2m} &= \min_{j}\{k_{2j}\}, \ k_{2M} &= \\ \max_{j}\{k_{2j}\}, \ k_{1M} &= \max_{j}\{k_{1j}\}, \ \varrho &= \max_{x_{1}\in\mathcal{Q}_{1}} \|x_{1}\|, \\ \mathcal{Q}_{1} &= \mathcal{Q}_{11} \cap \mathcal{Q}_{12}, \ \mathcal{Q}_{11} &= \{x_{1} \in \mathbb{R}^{n} : |x_{1j}| < \\ \bar{b}_{1j}/\bar{k}_{1j}, \ j &= 1, \dots, n\}, \ \mathcal{Q}_{12} &= \{x_{2} \in \mathbb{R}^{n} : |x_{2j}| \leq \\ L_{2j}/k_{2j}, \ j &= 1, \dots, n\}, \end{aligned}$$

=

<

 $\leq$ 

$$Q_1 = \begin{pmatrix} \bar{k}_{1m} & -\epsilon\mu_M \\ -\epsilon\mu_M & \mu_m \end{pmatrix}$$
$$Q_2 = \begin{pmatrix} k_{1M} + k_g & \epsilon\mu_M \\ \epsilon\mu_M & \mu_M \end{pmatrix}$$

$$Q_3 = \begin{pmatrix} \epsilon \bar{k}_{1m} & -\epsilon k_{2M}/2 \\ -\epsilon k_{2M}/2 & k_{2m} - \epsilon k_C \varrho - \epsilon \mu_M \end{pmatrix}$$

we have, on  $\mathcal{Q}_1 \times \mathcal{Q}_2$ , that

$$c_1 \|x\|^2 \le V_2(x) \le c_2 \|x\|^2$$
  
 $\dot{V}_2(x) \le -c_3 \|x\|^2$ 

with  $c_1 = \lambda_m(Q_1)/2 > 0$ ,  $c_2 = \lambda_M(Q_2)/2 > 0$  and  $c_3 = \lambda_m(Q_3) > 0$ , whence we conclude —by [11, Theorem 4.10]— that the origin  $(x_1, x_2) = (0_n, 0_n)$  is a (locally) exponentially stable equilibrium of the closed-loop system. The details omitted in this sketch of the proof of Corollary 3.1 will be thoroughly developed in future communications with more relaxed space limitations.

#### **4. SIMULATION RESULTS**

We implemented the proposed control scheme through numerical simulations considering the model of the 2-DOF revolute-joint mechanical manipulator used in [13], with dynamics characterized by

$$H(q) = \begin{pmatrix} 2.351 + 10.168 \cos q_2 & 0.102 + 0.084 \cos q_2 \\ 0.102 + 0.084 \cos q_2 & 0.102 \end{pmatrix}$$
$$C(q, \dot{q}) = \begin{pmatrix} -0.084\dot{q}_2 \sin q_2 & -0.084(\dot{q}_1 + \dot{q}_2) \sin q_2 \\ 0.084\dot{q}_1 \sin q_2 & 0 \end{pmatrix}$$
$$g(q) = \begin{pmatrix} 38.465 \sin q_1 + 1.825 \sin(q_1 + q_2) \\ 1.825 \sin(q_1 + q_2) \end{pmatrix}$$

Assumptions 2.1–2.3 are thus satisfied (this is a direct consequence of the revolute nature of both joints of the considered manipulator); in particular Assumption 2.3 is fulfilled with  $B_{g1} = 40.29$  Nm,  $B_{g2} = 1.825$  Nm and  $k_g = 40.37$  Nm/rad. Input saturation bounds are  $T_1 = 150$  Nm and  $T_2 = 15$  Nm, whence Assumption 2.4 is corroborated to be fulfilled with  $\eta = 3$ . For the sake of simplicity, units will be subsequently omitted.

The proposed design methodology was applied under the consideration of the following function definitions

$$\sigma_u(\varsigma;\beta,a) = \operatorname{sign}(\varsigma) \max\{|\varsigma|^\beta, a|\varsigma|\}$$
(24a)

$$\sigma_b(\varsigma;\beta,a,M) = \operatorname{sign}(\varsigma) \min\{|\sigma_u(\varsigma;\beta,a)|, M\} \quad (24b)$$

for constants  $\beta > 0$ ,  $a \in \{0, 1\}$ , and M > 0. Examples are shown in  $[1, \S5]$ .

We present a simulation test focusing on the comparison among the two types of convergence: finite-time vs exponential. The implementation was run taking the desired configuration at  $q_d = (\pi/4 \ \pi/2)^T$  [rad] and initial conditions as  $q(0) = \dot{q}(0) = 0_2$ . Based on the functions in Eqs. (24), we define, for every j = 1, 2,

$$\sigma_{ij}(\varsigma) = \sigma_b(\varsigma; \beta_i, a_{ij}, M_{ij}) \qquad i = 1, 2 \tag{25}$$

Fig. 1 Finite-time vs exponential stabilization

with  $a_{ij} = 0$ , i = 1, 2, j = 1, 2. Conditions on their parameters under which (9) is fulfilled are:

$$k_{1i} > k_a (2B_{ai})^{(1-\beta_1)/\beta_1} \tag{26a}$$

$$M_{1j} > 2B_{qj} \tag{26b}$$

Let us note, from the involved functions, as defined through Eq. (25), that  $B_j = M_{1j} + M_{2j}$ , j = 1, 2(see (8)). Thus, by fixing  $M_{11} = 82$ ,  $M_{21} = 18$ , and  $M_{12} = M_{22} = 6$ , (8) and (26b) are simultaneously satisfied. The control gain values were chosen taking care that inequality (26a) was satisfied.

Figure 1 shows results obtained taking  $\beta_1 = 1/2$ and  $\beta_2 = 2/3$ , and the control gains were taken, for both (finite-time and exponential) controllers, as:  $K_1 =$ diag[3255, 150] and  $K_2 =$  diag[150, 2]. One sees that the proposed scheme achieves both types of convergence avoiding input saturation, with the closed-loop trajectory arising through the exponential controller presenting a longer and more important transient. On the other hand, the finite-time stabilizer shows a more efficient ability to counteract the inertial effects through control signals with considerably less and lower variations during the transient.

## **5. CONCLUSIONS**

Global continuous control of mechanical systems with input constraints guaranteeing finite-time or exponential stabilization has been made possible and further simplified through desired conservative-force compensation. This controller is not a simple extension of the on-line compensation case but it has rather proven to need more involved requirements resulting from a closed-loop analysis with considerably higher degree of complexity. Simulation results have shown the actual ability of the proposed approach to guarantee the considered types of convergence avoiding input saturation, with finite-time control signals giving rise to less and lower variations during the transient. A more detailed implementation test study focusing on further aspects on the closed-loop performance is intended to be presented on future communications with more relaxed space restrictions.
